The water cycle

Original teaching fixture. Shared under the repository MIT License.

Water moves between the ground, living things, and the air.

Evaporation: energy from the Sun helps liquid water become water vapor.

Condensation: cooling water vapor forms tiny liquid droplets in clouds.

Precipitation: water returns to the ground as rain, snow, or hail.

Collection: water gathers in rivers, lakes, oceans, and the ground.

Try this: draw four boxes and label the four stages above.

Explain how the Sun helps water move from a puddle into the air.

Source limits: this one-page fixture contains text only.

It contains no measured experiment, photograph, or second page.
